

INTRODUCTION TO PANDAS DATAFRAMES

Plan for the next few lectures:

- Introduce the pandas DataFrame object and discuss its purpose
- Create several DataFrames from scratch
- Relate what you have already learnt to what's written in the pandas documentation

The Pandas DataFrame : Introduction

Series

Series

DataFrame

The Pandas DataFrame : Introduction

Series

DataFrame

The Pandas DataFrame : Introduction

A vertical column of five empty rectangular cells, representing a single column of data in a Pandas Series.

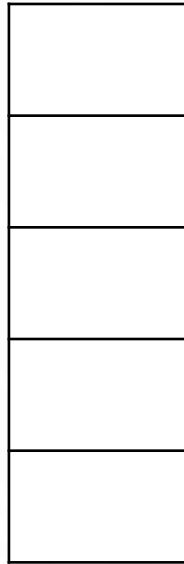

Series

A grid of 15 empty rectangular cells arranged in 5 rows and 3 columns, representing a two-dimensional data structure in a Pandas DataFrame.

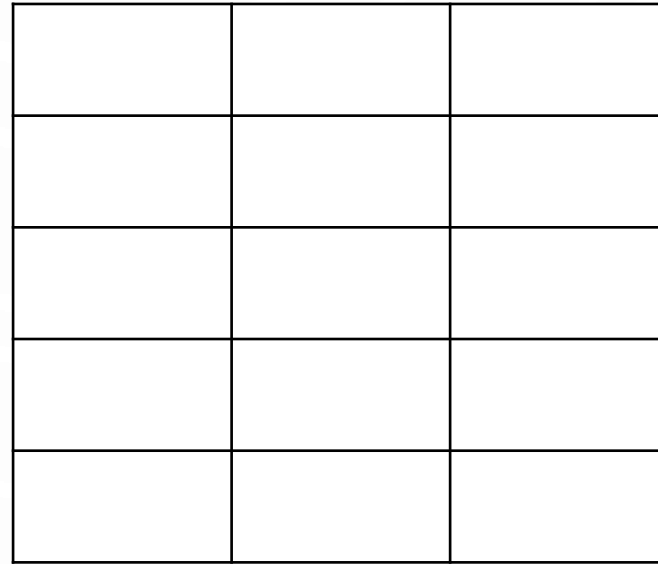

DataFrame

The Pandas DataFrame : Introduction

A diagram of a Pandas Series, represented as a single vertical column with five empty rectangular cells.

Series

A diagram of a Pandas DataFrame, represented as a grid with 5 rows and 3 columns, totaling 15 empty rectangular cells.

DataFrame

The Pandas DataFrame : Introduction

Single column data

- corresponds to a **single variable**
- information of a **single type**
- we can preserve **data consistency**

Series

Multi-column data

- each column represents a **different** variable
- every column contains data of **its own type**
- the information can potentially **be heterogeneous**
- we can preserve **data consistency**
(we aim for having information of the same type **within** a certain column)

DataFrame

Series

DataFrame

Any characteristic of a Series, is also applicable to the separate columns of a DataFrame.

Series

DataFrame

One-dimensional data structure

- contains values along **a single** axis (rows)

rows

Series

Two-dimensional data structure

columns

rows

DataFrame

- contains values along **two** axes (rows and columns)
- represents a **tabular** structure
- it is the closest Python analogue to a standard two-dimensional dataset, or a spreadsheet
- can have both row and column **labels**

Two-dimensional data structure

DataFrame

- contains values along **two** axes (rows and columns)
- represents a **tabular** structure
- it is the closest Python analogue to a standard two-dimensional dataset, or a spreadsheet
- can have both row and column **labels**

2-D Matrix = **Two-dimensional NumPy array** = **Two-dimensional data structure**

DataFrame

- contains values along **two** axes (rows and columns)
- represents a **tabular** structure
- it is the closest Python analogue to a standard two-dimensional dataset, or a spreadsheet
- can have both row and column **labels**

2-D Matrix = **Two-dimensional NumPy array** = **Two-dimensional data structure**

	var 1	var 2	var 3
observation 1			
observation 2			
observation 3			
observation 4			
observation 5			

DataFrame

- contains values along **two** axes (rows and columns)
- represents a **tabular** structure
- it is the closest Python analogue to a standard two-dimensional dataset, or a spreadsheet
- can have both row and column **labels**

2-D Matrix = **Two-dimensional NumPy array** = **Two-dimensional data structure**

	var 1	var 2	var 3
observation 1			
observation 2			
observation 3			
observation 4			
observation 5			

DataFrame

- contains values along **two** axes (rows and columns)
- represents a **tabular** structure
- it is the closest Python analogue to a standard two-dimensional dataset, or a spreadsheet
- can have both row and column **labels**

DataFrame

Series and DataFrames as Programming Objects

A Powerful Version of the Python List

+ Python Dictionary Features

- Its indexing relates to **the keys of a dictionary**
- It also allows us to extract the desired parts of the given dataset more quickly and efficiently

Series

An Enhanced Python Dictionary

DataFrame

- We can provide a whole object that contains the values of an entire column **to the dictionary keys**
- Inherits the characteristics of the Dictionary class
- Plus a lot more features and functionalities
